Abstract

This paper presents a framework for norm-based capacity control with respect to a Weight-Normalized Residual Neural Networks (ResNets). We first formulate the representation of each residual block. For the regression problem, we analyze the Rademacher Complexity of the ResNets family and establish a tighter generalization upper bound for Weight-Normalized ResNets. Using the $\ell_{p,q}$-norm weight normalization in which $1/p + 1/q \geq 1$, we discuss the properties of a width-independent capacity control, which only relies on the depth according to a square root term. Several comparisons suggest that our result is tighter than previous work. Parallel results for Deep Neural Networks (DNN) and Convolutional Neural Networks (CNN) are included by introducing the $\ell_{p,q}$-norm weight normalization for DNN and the $\ell_{p,q}$-norm kernel normalization for CNN. Numerical experiments also verify that ResNet structures contribute to better generalization properties.

1 Introduction

Deep neural networks have been applied to many fields, including computer vision, speech recognition, natural language processing, audio recognition, social network filtering, machine translation, and more. Since ResNets have been introduced to improve imag recognition [He et al., 2016], [Goodfellow et al., 2016], ResNets have taken the deep learning world by storm. Though the robustness and efficiency of ResNets has proven to be enormously successful in various artificial intelligence tasks [Huang et al., 2017], [Srivastava et al., 2015], [Fan et al., 2018], we aim to examine the capacity of ResNets theoretically. Previous studies have investigated the capacity of several simple network structures, such as unregularized DNN, DNN without bias or DNN with ReLU active functions [Bartlett et al., 2017], [Golowich et al., 2018a]. [Neyshabur et al., 2017], [Neyshabur et al., 2015], [Sun et al., 2016], [Shalev-Shwartz and Ben-David, 2014].

ResNets and other powerful structures, however, require further explorations in literature.

Intuitively, great robustness should be compatible with relatively small generalization bounds. Inspired by the amazing performance of ResNets in regression problems, we hope to answer a central question: can we find a tighter generalization bound for ResNets and other developed structures?

In this paper, we focus on providing a tighter generalization bound with respect to $\ell_{p,q}$-norm for ResNets. Since most prior studies are restricted to simple DNN structures [Golowich et al., 2018b], [Bartlett et al., 2017], [Neyshabur et al., 2017], [Sun et al., 2016], we take the layer-wise weight normalization and hidden layers with bias into consideration to pursue a more general sight. After showing comparisons with some related works, further discussions extend the parallel conclusions to DNN cases.

We first formulate the function class, which is derived from the combination of Residual-Blocks, and define the $\ell_{p,q}$-weight normalization. After providing an upper bound for the Rademacher Complexity for the ResNets function class, we induce the generalization bound with respect to regression problems. In particular, we obtain a width-free generalization bound with $1/p + 1/q \geq 1$; therefore, several prior conclusions under $\ell_{2,2}$-norm, $\ell_{1,\infty}$-norm are covered. By utilizing the same method, we extend the width-free generalization bound to DNN and Convolutional-ResNets nontrivially.

The contributions of this paper are summarized as follows: 1. We obtain a tighter generalization bound for ResNets with layer-wise $\ell_{p,q}$-normalization and bias; 2. We justify the tightness by comparing the results with related works; 3. We extend the parallel conclusions to structures, including DNN and Convolutional-ResNets.

In Section 2, we introduce some notations as well as the formulation of the ResNets function class. To prepare for the main result, we provide the upper bound of the Rademacher Complexity for the ResNets function class. Section 4 discusses the generalization bound for ResNets and several comparisons. We explore the parallel conclusions of DNN and Convolutional-ResNets in Section 5 and Section 6, respectively. In Section 7, numerical experiments are explained to verify the previous theoretical results. The proof details are concluded in the supplementary materials. [Mo and Chen, 2019]
2 Preliminary

Traditionally, ResNets refer to networks with forms similar to Figure 1: By adding bias to each hidden layers, we obtain a representation of the mapping of a single residual-block as:

\[ F_i(x_{i-1}) = \sigma(W_{i,2} \cdot \sigma([W_{i,1} \cdot x_{i-1} + b_{i,1}]) + b_{i,2} + I_i \cdot x_{i-1}) \]

where \( F_i : \mathbb{R}^{d_{i-1} \times 2} \rightarrow \mathbb{R}^{d_i \times 2} \). The bias is forced to be commensurate with the weight matrix in terms of dimension. In order to simplify \( F_i \), we rewrite the function as:

\[ \tilde{F}_i(x_{i-1}) = \sigma(W_{i,2} b_{i,2}) \cdot \sigma(W_{i,1} b_{i,1}) + I_i x_{i-1} \]

\[ = \sigma(W_{i,2} b_{i,2}) \cdot \sigma(W_{i,1} b_{i,1}) + I_i x_{i-1} \]

By denoting every \( \tilde{x}_i \triangleq (x_i) \), \( \tilde{M}_{i,j} \triangleq (W_{i,j} b_{i,j}) \), and \( \tilde{M}_{i,j}^T \triangleq (\tilde{M}_{i,j} e_d^T) \), we rewrite \( \tilde{F}_i : \mathbb{R}^{d_{i-1} \times 2} \rightarrow \mathbb{R}^{d_i \times 2} \) as:

\[ \tilde{F}_i(\tilde{x}_{i-1}) = \sigma(\tilde{M}_{i,2} \cdot \sigma(\tilde{M}_{i,1} \cdot \tilde{x}_{i-1}) + I_i \cdot \tilde{x}_{i-1}) \]

The introduced notations are unambiguous:

1. \( M_{i,j}, \tilde{M}_{i,j} \): \( M_{i,j} \in \mathbb{R}^{d_i \times d_{i-1}}, \tilde{M}_{i,j} \in \mathbb{R}^{d_i \times d_{i-1}} \).
2. \( I_i \): \( I_i \in \mathbb{R}^{d_i \times d_{i-1}} \), instead of the Identity matrix, \( I_i \) is introduced to ensure that \( I_i \cdot x_{i-1} \) is commensurate with \( M_{i,j} \cdot x_{i-1} \) in terms of dimension.
3. \( \tilde{M}_{i,j}^T \): A \( \ell_{p,q} \)-norm vector.
4. \( \ell_{p,q} \)-norm: The \( \ell_{p,q} \)-norm of a \( n \times m \) matrix \( A \) is defined as \([A]_{p,q} = \left( \frac{1}{m} \sum_{j=1}^m |a_{ij}|^p \right)^{\frac{1}{p}}\).

We denote the last weight layer and the corresponding matrix as \( \tilde{F}_{k+1} : \mathbb{R}^{d_{k+1} \times 2} \rightarrow \mathbb{R}^{d_{k+1} \times 2} \) and \( \tilde{M}_{k+1} \in \mathbb{R}^{d_{k+1} \times (d_k + 1)} \), where \( \tilde{M}_{k+1} \triangleq (W_{k+1}, b_{k+1}) \). With \( \ell_{p,q} \)-norm, the weight matrices \( \{M_{i,j} \}_{i,j=1}^{k+1} \) are constrained by \( \|M_{i,j}\|_{p,q} \leq c_{i,j}, \forall i = 1, \ldots, k+1 \). The discussion above induces a function class called the Weight-Normalized-Residual-Network class, which contains elements that can be represented by combining residual-blocks.

Definition 2.1. \( \mathcal{R}_{p,q,c}^{k,d} \). This definition depicts a class of functions that can be represented by the previously mentioned WN-RN structure.

\[ \text{p: The norm is set as } \ell_{p,q} \text{-norm} \]

\[ \text{d: } d \triangleq (d_{k+1}, d_{k,2}, d_{k,1} \ldots d_{1,2}, d_{1,1}, d_0) \text{ is a vector with width information.} \]

We denote \( d_{i,1}, d_{i,2} \) as the width of the 1st and 2nd layer of the \( i \)-th residual block, respectively.

\[ \text{c: } c \triangleq (c_{k+1}, c_{k,2}, c_{k,1} \ldots c_{1,2}, c_{1,1}), \text{ where } \|M_{k+1}\|_{p,q} \leq c_{k+1}, \|M_{k,2}\|_{p,q} \leq c_{k,2}, \|M_{i,1}\|_{p,q} \leq c_{i,1}, \forall i = 1, \ldots, k; \]

\[ f \in \mathcal{R}_{p,q,c}^{k,d} \triangleq \exists \{M_{i,1}, M_{i,2}\}_{i=1}^{k+1}, \exists t. f = \tilde{F}_{k+1} \circ \tilde{F}_k \circ \cdots \circ \tilde{F}_1. \]

By definition, the following theorem is obvious:

Theorem 2.2. The property of \( \mathcal{R}_{p,q,c}^{k,d} \).

1. \( \mathcal{R}_{p,q,c}^{k,d} \subset \mathcal{R}_{p,q,c}^{k,2d} \)
2. \( \mathcal{R}_{p,q,c}^{k,d} \subset \mathcal{R}_{p,q,c}^{k+1,d} \)

Intuitively, a shallow and thin ResNet can be represented by a relative deeper and wider one.

3 The Estimation of the Rademacher Complexity for \( \mathcal{R}_{p,q,c}^{k,d} \)

In this section, we provide an upper bound for the Rademacher Complexity of \( \mathcal{R}_{p,q,c}^{k,d} \).

Definition 3.1. Rademacher Complexity of a function class.

Assume that \( f \) is a real value function, \( \epsilon_i \) is the Rademacher Random Variable:

1. Empirical Rademacher Complexity:

\[ \hat{r}_n(N) \triangleq E_n \left[ \sup_{f \in N} \frac{1}{n} \sum_{i=1}^n \epsilon_i f(z_i) \right] \]

2. Rademacher Complexity:

\[ r_n(N) \triangleq E_{\mathcal{S} \sim \Delta(S)} \left[ \hat{r}_n(N) \right] \]

Without a loss of generality, we consider the input space as \( \mathcal{X} \triangleq \{x \in \mathbb{R}^d : |x|_{\infty} \leq 1 \} \). Moreover, we assume that \( d_{k+1} = 1 \), so that the Rademacher Complexity is well defined.

Theorem 3.2. The Rademacher Complexity of \( \mathcal{R}_{p,q,c}^{k,d} \).

If \( \rho \geq 1, q \geq 1, k \geq 0 \) and \( c > 0 \), \( \rho \) is the lipschitz constant of the active function; \( d_{i,j} \in \mathbb{N}^+ \), \( \forall i = 1, \ldots, k, j = 1, 2 \).
Then, for every set of $S = \{x_1, \ldots, x_n\} \subset \mathcal{X}$, we obtain:

$$
\mathcal{N}_{\text{res}}(\mathcal{R}^n_{p,q,e}) \\
\leq c_{k+1} d_{k+1} \left( \log \frac{(k+4)!}{n} \right)^{\frac{1}{k}} \\
+ \frac{1}{k} \left\{ \left( c_{i,j}^2 \rho^2 d_{i,j}^2 \right)^{\frac{1}{p-\frac{1}{q}}} + 1 \right\} d_0 \left( \frac{\sqrt{C(p)}}{n} \right).
$$

where $s_0 = d_0^\frac{1}{p}$,

$$s_i = \left( c_{i,j}^2 \rho^2 d_{i,j}^2 \right)^{\frac{1}{p-\frac{1}{q}}} + 1 s_{i-1} \\
+ c_{i,j}^2 \rho^3 d_{i,j}^3 \left( \frac{1}{p} - \frac{1}{q} \right)^{\frac{1}{q}} + c_{i,j} d_{i,j} \left( \frac{1}{p} - \frac{1}{q} \right)^{\frac{1}{q}} + 1
$$

for $i = 1, 2, \ldots, k$.

$C(p) \triangleq \left\{ \begin{array}{ll}
2 \log(2d_0) \\
\min(p^* - 1, 2 \log(2d_0)) & p = 1,
\end{array} \right.$

We prepare this theorem for the main result. According to [Mohri et al., 2012], the generalization bound can be deduced from the upper bound of the Rademacher Complexity.

4 The Generalization Bound for Weight-Normalized-ResNets

In this section, we provide an estimation for the generalization bound in the data regression problem. With $\ell_{p,q}$-norm satisfying $\frac{1}{p} + \frac{1}{q} \geq 1$, the estimation has a more laconic form.

The Regression Problem

$S \triangleq \{(x_1, y_1), \ldots, (x_n, y_n)\} \sim D$ are i.i.d samples in $\mathcal{X} \times \mathcal{Y} \subset \mathbb{R}^{d_0+1}$. We are interested in finding $h : \mathcal{X} \rightarrow \mathcal{Y}$ in order to satisfy $y_i = h(x_i) + \epsilon_i, \forall i = 1, \ldots, n$, where $\epsilon_i$ represents independent noise. To evaluate the choice of $h$, we introduce the loss function class:

**Definition 4.1. Loss Function Class $\mathcal{R}^{n,k}_{p,q,e}$:**

$$\mathcal{R}^{n,k}_{p,q,e} \triangleq \{g(f(x), y) \in \mathbb{R}[x \in \mathcal{X}, y \in \mathcal{Y}, f \in \mathcal{R}^{n,k}_p]\}$$

If we assume that $\forall g \in \mathcal{R}^{n,k}_{p,q,e} : \mathcal{Y} \times \mathcal{Y} \rightarrow [0, 1]$ is a $\gamma$-Lipschitz function, the Loss Function Class is denoted as $\mathcal{R}^{n,k}_{p,q,e}$.

**Definition 4.2. Generalization Error:**

If $\forall g \in \mathcal{R}^{n,k}_{p,q,e}$, the true risk and the empirical risk is defined as:

$$E_D[g] \triangleq E_{(x,y)} \sim D \left[ g(x, y) \right],$$

$$\mathbb{E}_{D}[g] \triangleq \frac{1}{n} \sum_{i=1}^{n} g(f(x_i), y_i).$$

The generalization error is the deviation between the expected and the empirical error:

$$\mathbb{E}[g] - \mathbb{E}_{D}[g] \forall g \in \mathcal{R}^{n,k}_{p,q,e}.$$

Generalization bound is an upper bound for generalization error. Intuitively, high generalization error indicates that the model is overfitting. Hence, generalization bound guarantees generalization error to be lower than a controllable level. In other words, generalization bound provides us with an explicit guidance to avoid overfitting. A tight generalization bound promises that a network can fit the unseen data well.

4.1 Main Results

**Theorem 4.3. Estimation of Generalization Bound:**

We assume that $z \triangleq (x, y) \sim D, S \triangleq \{z_1, \ldots, z_n\}$ is a dataset with $n$ i.i.d samples selected from the distribution $D$. Then, we fix $\delta \in (0, 1), \forall k \in \mathbb{N}^+, \forall d_{i,j} \in \mathbb{N}^+, i = 1, \ldots, k, j = 1, 2$. With probability of at least $1 - \delta$ over the generation of $S$, it holds that:

$$\sup_{g \in \mathcal{R}^{n,k}_{p,q,e}} \| \mathbb{E}[g] - \mathbb{E}_{D}[g] \| \\
\leq \sqrt{\frac{\log \left( \frac{1}{\delta} \right)}{2n} + 2\gamma c_{k+1} \rho d_{k+1} \left( \frac{1}{p} - \frac{1}{q} \right)^{\frac{1}{q}} + 1 \frac{\sqrt{C(p)}}{n}}.$$
Corollary 4.5. Generalization Bound in General Cases.
We assume that \( z \sim (x, y) \sim D \), \( S \sim \{z_1, \ldots, z_n\} \) is a dataset with \( m \) i.i.d samples selected from the distribution \( D \). Then, we fix \( \delta \in (0, 1), \forall k \in \mathbb{N}^+, \forall d_j \in \mathbb{N}^+, j = 1, \ldots, k \). With probability of at least \( 1 - \delta \) over the generation of \( S \), it holds that:

\[
\sup_{g \in \mathcal{G}_\gamma} \left| E_D[g] - \bar{E}_S[g] \right| \\
\leq c_{k+1}\rho d^{p;q} \left( \frac{1}{2k+1} \sum_{i=1}^{k} h_i + \sum_{i=1}^{k} h_i \right) \\
+ \frac{1}{h_i} \prod_{i=1}^{k} \left( \prod_{i=1}^{h_i} c_{i,j} + 1 \right) \frac{1}{h_i} \sqrt{C(p)} \frac{1}{n},
\]

where \( s_0 = \frac{d^{p;q}}{\gamma} \), for \( i = 1, 2, \ldots, k \),

\[
s_i = \left( \prod_{j=1}^{h_i} c_{i,j} + 1 \right) s_{i-1} + \sum_{j=1}^{h_i} c_{i,j}.
\]

When we set ReLU or another homogeneity function as activation functions, the corresponding upper bound \( \{c_{i,j}\}_{i=1}^{h_i} \) and \( \{c_{i,j}^{\prime}\}_{i=1}^{h_i} \) hold \( \prod_{i=1}^{h_i} c_{i,j} = \prod_{i=1}^{h_i} c_{i,j}^{\prime} \). We can obtain a tighter bound with \( s_0 = \frac{d^{p;q}}{\gamma}, s_i = \left( \prod_{j=1}^{h_i} c_{i,j} + 1 \right) s_{i-1} + \sum_{j=1}^{h_i} c_{i,j}, \forall i = 1, 2, \ldots, k \), by taking \( c_{i,1}, \ldots, c_{i,2} \to 0^+ \).

4.2 Comparisons
We focus on the term \( \mathcal{R}_n(\mathcal{R}_G) \) with \( p = q = 2, \rho = 1 \):

\[
\mathcal{R}_n(\mathcal{R}_G) \\
= O \left\{ \gamma \sqrt{k} \cdot \prod_{i=1}^{k-1} (c_{i+1}) \cdot \left( 2 \frac{6k \log 2}{n} + \sqrt{C\left( \frac{p}{\gamma} \right)} \right) \right\}
\]

\[
\approx O \left\{ \gamma c_k \cdot \prod_{i=1}^{k} (c_{i+1}) \cdot \frac{\sqrt{k}}{n} \right\}.
\]

A recent conclusion [Li et al., 2018] argues that:

\[
\mathcal{R}_n(\mathcal{R}_G) = O \left\{ \left( \frac{d_1 d_2 \log \min_j \{B_{j,1}, B_{j,2}\} \gamma \sqrt{k} \cdot \max_j \{B_{j,1}, B_{j,2}\} \min_j \{B_{j,1}, B_{j,2}+1\} \right)^{\frac{1}{2}} \cdot \gamma \cdot \prod_{j=1}^{k} \left( B_{j,1} B_{j,2} + 1 \right) \cdot \frac{\sqrt{k}}{n} \right\}
\]

where \( B_{j,1} \) is the upper bound of \( \left\| M_{j,1} \right\|_{2,2} \) with bias \( B_{j,1} = 0, j = 1, \ldots, k \). The widths of the 1st and 2nd layer in the \( j \)th residual-block are denoted as \( d_1, d_2 \), respectively. Since \( c_j \leq B_{j,1}, B_{j,2}, \forall j = 1, \ldots, k \), we obtain a tighter generalization bound for the ResNets structures with bias, which can be extended from the Frobenius Norm to a general \( \ell_{p,q} \)-norm.

The comparison shows that our generalization bound is tighter than [Li et al., 2018]’s, which is the tightest previous generalization bound for ResNets and DNN. Comparisons between [Li et al., 2018]’s work and previous work are included in that paper. While [Li et al., 2018]’s work is restricted to Frobenius-norm, we generally obtain generalization bound with respect to \( \ell_{p,q} \)-norm.

5 Parallel Extensions for Weight-Normalized DNN

Using the same methods, our conclusions can be extended to Deep Neural Networks. We introduce the definition of the DNN function class as, \( \mathcal{T}_i : \mathbb{R}^{d_i+1} \rightarrow \mathbb{R}^{d_i+1}, \mathcal{T}_i(\begin{pmatrix} x \end{pmatrix}) \triangleq \sigma(\begin{pmatrix} W_i & b_i \end{pmatrix} \begin{pmatrix} x \end{pmatrix}), \forall x \in \mathbb{R}^{d_i+1} \).

We also introduce the notation as, \( U_i \triangleq (\begin{pmatrix} W_i & b_i \end{pmatrix}, 1) \). By sharing several notations, \( \mathcal{T}_{k+1}, \mathcal{M}_{k+1}, c, d, k, n \), we obtain the parallel definitions:

**Definition 5.1.** \( \mathcal{N}_{p,q}^{k,d} \) This definition describes the class of functions \( f \) that can be represented by DNN.

\( p,q : \text{the norm is set as } \ell_{p,q} \)-norm.

\( d : \text{d} = (d_1, \ldots, d_k,d_0) \) is a vector with width information.

\( c : c \triangleq (c_{k+1}, c_k, c_{k-1}, \ldots, c_1) \), where \( \|U_i\|_{p,q} \leq c_i, \forall i = 1, \ldots, k + 1 \). \( f \in \mathcal{N}_{p,q}^{k,d} \iff \exists \{U_i\}_{i=1}^{k+1}, \text{s.t. } f = \mathcal{T}_{k+1} \circ \mathcal{T}_k \circ \cdots \mathcal{T}_1 \).

**Theorem 5.2.** The properties of \( \mathcal{N}_{p,q}^{k,d} \)
Since we have \( p, q, c^{(1)} \), \( c^{(2)} \), \( k_1, k_2 \) and vectors \( d^{(1)}, d^{(2)} \) with \( k_1 \leq k_2 \), \( d^{(1)} \leq d^{(2)} \), \( c^{(1)} \leq c^{(2)} \) w.r.t the components precedes the \( k_1 \)-th component:

1. \( \mathcal{N}_{p,q}^{k_1,d^{(1)}} \subset \mathcal{N}_{p,q}^{k_2,d^{(2)}} \)
2. \( \mathcal{N}_{p,q}^{k_1,c^{(1)}} \subset \mathcal{N}_{p,q}^{k_2,c^{(2)}} \).

**Definition 5.3.** The Loss Function Class \( \mathcal{G}_{p,q}^{k,d} \)
\( \mathcal{G}_{p,q}^{k,d} \triangleq \{g(f(x), y) : x \in X, y \in Y, f \in \mathcal{N}_{p,q}^{k,d}\}. \)

If we assume that \( \forall g \in \mathcal{G}_{p,q}^{k,d} : \gamma \times \gamma \rightarrow [0, 1] \) is a \( \gamma \)-Lipschitz function, the Loss Function Class is denoted as \( \mathcal{G}_\gamma \triangleq \{g \text{ is } \gamma \text{-Lipschitz} : g \in \mathcal{G}_{p,q}^{k,d}\}. \)

**Theorem 4.4. An Estimation of Generalization Bound.**

We assume that \( z \sim (x,y) \sim D \), \( S \sim \{z_1, \ldots, z_n\} \) is a dataset with \( m \) i.i.d samples selected from the distribution \( D \). Then, we fix \( \delta \in (0, 1), \forall k \in \mathbb{N}^+, \forall d_j \in \mathbb{N}^+, j = 1, \ldots, k \). With probability of at least \( 1 - \delta \) over the generation of \( S \), \( s_{k+1} \triangleq \sum_{i=1}^{k+1} \left( \prod_{i=1}^{k} c_{i} \rho d_i^{p+1/q} \right) + \frac{d_0^{p+1/q}}{\sum_{i=1}^{k+1} c_{i} \rho d_i^{p+1/q}} \), it holds that:

\[
\sup_{g \in \mathcal{G}_\gamma} \left| \mathbb{E}_D[g] - \bar{E}_S[g] \right| \\
\leq \left( \frac{\sqrt{k}}{2n} \right) \gamma + 2 \gamma \cdot \left( s_{k+1} \frac{\sqrt{(2k+4) \log 2}}{n} \right) + \frac{\sqrt{k}}{\sum_{i=1}^{k+1} c_{i} \rho d_i^{p+1/q}} \gamma \cdot \left( \frac{C(p)}{n} \right).
\]

**Corollary 5.5.** The Generalization Bound with \( \frac{1}{p} \) or \( \frac{1}{q} \) \( \geq 1 \).

We assume that \( z \sim (x,y) \sim D \), \( S \sim \{z_1, \ldots, z_n\} \) is a
Then, we fix $\delta \in (0, 1)$, $\forall k \in \mathbb{N}^+$, $\forall d_i \in \mathbb{N}^+$, $i = 1, \ldots, k$. With probability of at least $1 - \delta$ over the generation of $S$, it holds that:

$$
\sup_{g \in \mathcal{G}_S} \left| \mathbb{E}_D[g] - \hat{\mathbb{E}}_S[g] \right| \\
\leq \frac{\log(\frac{1}{\delta})}{2n} + 2\gamma \left( \sum_{i=1}^{k+1} d_i \prod_{l=1}^{i-1} c_{l} + d_0 n \prod_{l=1}^{k} c_{l} \rho \right) \\
\cdot \left( \frac{(2k + 4) \log 2}{n} + \frac{1}{n} \sum_{j=1}^{k+1} c_{j} \rho d_0 \sqrt{\frac{C(p)}{n}} \right).
$$

With ReLU as activation function, we obtain:

$$
\sup_{g \in \mathcal{G}_S} \left| \mathbb{E}_D[g] - \hat{\mathbb{E}}_S[g] \right| \\
\leq \frac{\log(\frac{1}{\delta})}{2n} + 2\gamma \left( \sum_{i=1}^{k+1} d_i \prod_{l=1}^{i-1} c_{l} \rho \right) \sqrt{\frac{(2k + 4) \log 2}{n}} \\
+ \frac{1}{n} \sum_{j=1}^{k+1} c_{j} \rho d_0 \sqrt{\frac{C(p)}{n}}.
$$

Comparisons:

We focus on the term $\mathcal{R}_n(\mathcal{G}_S)$ with $p = q = 2, \rho = 1$:

$$
\mathcal{R}_n(\mathcal{G}_S) = \mathcal{O}\left\{ \gamma \left( \sum_{i=1}^{k} \prod_{l=1}^{i} c_{l} \right) \sqrt{\frac{k \log 2}{n}} \right\} \\
+ \frac{1}{n} \sum_{j=1}^{k} c_{j} \sqrt{\frac{C(p)}{n}}.
$$

A recent conclusion [Li et al., 2018] argues that:

$$
\mathcal{R}_n(\mathcal{G}_S) = \mathcal{O}\left\{ \gamma_{k+1} \cdot \left( \sum_{j=1}^{k+1} B_j \cdot \left( d^2 \cdot \log \left( \gamma \sqrt{n} \cdot \max_j B_j \right) \cdot \frac{\sqrt{k}}{n} \right) \right) \right\},
$$

where $B_j$ is the upper bound of the corresponding $\|U_j\|_{p,q}$, with bias $b_j = 0$, $j = 1, \ldots, k$; $i = 1, 2$. The widths of the $j$th layer is denoted as $d$. We obtain a tighter generalization bound for DNN structures with bias, which can be extended from the Frobenius Norm ($p = q = 2$) to a general $\ell_{p,q}$-norm.

For DNN, our result is tighter than [Xu and Wang, 2018]'s, since our $2(k + 2)\log 2$ is smaller than their $(k + 1)\log 16$. Moreover, the normalization bounds $\{c_i\}_{i=1}^k$ need not to be the same value and the weight normalization constrains are inequalities rather than equalities. Hence, our generalization bound is tighter and more general than Xu Y’s.

6 Parallel Extensions for Kernel-Normalized CNN

Our conclusions can be extended to CNN cases, since a convolutional connection is tantamount to a full connection with sparse matrix. In this section, we represent the CNN structure by reducing the convolution blocks to a combination of linear functions and active functions.

In image recognition tasks, we feed a CNN with image data (pixel matrixes and RGB channels). To obtain a similar form as Section 4 and 5, we reshape the input matrixes for each layers as vectors. In practice, we rarely adopt networks that consist only of convolutional connection blocks. Without a loss of generality, we focus on a single convolution connection block. Hence, we introduce the following notations.

**Definition 6.1.** The size of input image: $w_1 \times w_2$.

The number of input and output channels: $v_{in}, v_{out}$.

The size of kernels: $u$.

For convenience, we reshape the image data as: $x[l] = \text{image}^m_{v_1} \cdot \text{image}^m_{v_2} \cdot \text{image}^m_{v_3} \cdot \text{image}^m_{v_4}$, for $l = (m_3 - 1)w_1 w_2 + (m_2 - 1)w_1 + m_1$, $1 \leq m_1 < v_{in}$, $1 \leq m_2 \leq w_2$, $1 \leq m_3 < w_1$. This suggests that $x[l]$ corresponds to the element at the $m_1$th row and $m_2$th column of the kernel in the $m_3$th channel. Thus, we define the row of the weight matrix as:

$$
V^{(k)}_{i,j}(l) = \begin{cases} 
\mathcal{K}^{(m_1,k)} \cdot \text{image}^m_{v_3} \cdot \text{image}^m_{v_4} \\
0
\end{cases},
$$

where $\mathcal{K}^{(m_1,k)}$ is the $m_1$th kernel in $k$th channel.

$$
A(m_1, m_2, m_3) = \begin{cases} 
\{ a \mid a = (m_1 - 1)w_1 w_2 + (m_2 - 1)w_1 + m_3, \\
1 \leq m_1 < v_{in}, 1 \leq m_2 \leq j + u - 1, 1 \leq m_3 \leq i + u - 1 \}
\end{cases}.
$$

By definition, the $\ell_p$-norm of $V^{(k)}_{i,j}$ is $\| \mathcal{K}^{(1,k)} \|_p$, $\mathcal{K}^{(2,k)} \|_p$, $\ldots$, $\mathcal{K}^{(v_{in},k)} \|_p$. With a fixed value for $k$, there are $w_1 w_2$ rows; therefore, we can represent the $\ell_{p,q}$-norm of matrix $M$ as:

$$
\| M \|_{p,q} = \sum_{l=1}^{v_{out}} \| (\mathcal{K}^{(1,l)}, \mathcal{K}^{(2,l)}, \ldots, \mathcal{K}^{(v_{in},l)}) \|_p. 
$$

If we constraint each kernel as $\| \mathcal{K} \|_p \leq \hat{c}$, then

$$
\| M \|_{p,q} \leq \hat{c} (w_1 w_2) \frac{1}{2}.
$$

In these cases, we prefer kernel normalization to weight normalization. By substituting the normalization-bound $c$ in Chapter 3 with $(v_{in})^\frac{p}{2} + 1 \frac{1}{2} (w_1 w_2) \frac{1}{2}$, we extend our conclusion to apply to CNN cases. Moreover, $c$ can be rewritten as $\hat{c} (w_1 w_2)^\frac{1}{2}$ when we set the bias as 0.

7 Numerical Experiments

In this section, we discuss numerical experiments that implies the generalization properties of ResNets is better than DNN’s. In particular, we train two simple networks to solve a regression problem and calculate the generalization bound for the networks. While both of the networks share the same initialization and parameters, a residual shortcut is added to the second network.

Intuitively, we hypothesize that ResNets has the capacity to generalize better than DNN.
7.1 Experiment Settings

Dataset
We convey our experiment on a non-linear regression problem: \( y = \frac{1}{1 + \exp(-t)} \), \( t = 1^T x + \cos(1^T x) \). We sample 500 random samples \( \{(x_i, y_i)\}_{i=1}^{500} \subset \mathbb{R}^{300} \times \mathbb{R} \) for training set, and 1500 samples for testing set from the following procedure.
1. Independently sample an auxiliary variable \( z_i \in \mathbb{R}^{300} \) from \( N(0, 1) \).
2. Generate \( x_i \) by \( x_i[1] = z_i[1] \), \( x_i[j] = z_i[j] + 0.2(z_i[j-1] + z_i[j+1]) \), for \( j = 2, ..., 300 \).
3. Compute \( y_i = \frac{1}{1 + \exp(-t_i)} \), \( t_i = 1^T x_i + \cos(1^T x_i) \) for \( i = 1, ..., 500 \) (for \( i = 1, ..., 1500 \) for test dataset).

Network Model
We first set Net-A and Net-B as two fully connected DNNs with four hidden layers. Then, we add a residual shortcut to Net-B between the second layer and the third one. The parameters are shown in Figure 2. Through the course of several experiments, we found that the choice of widths did not affect the general conclusion; hence, we selected the width parameters arbitrarily.

We first initialize the weights of Net-A by the Xavier Initialization and set all the bias components as \( 0 \). As a control group, Net-B shares all the initialized parameters with Net-A. We vary the scale of the initialization before training by dividing the weights from the Xavier Initialization by the ‘scale’. Then, we adopt Mean Square Loss as loss function and ReLU as active functions.

After training Net-A and Net-B with the same strategy, we calculate the \( \ell_{2,2} \)-norm of their weights, respectively. By Theorems 4.3, 5.4, we compare the generalization bound of the two models (\( A_{GB} \) and \( B_{GB} \) for short). \( A_{GB} > B_{GB} \) suggests that the ResNets structure has a relatively lower generalization bound while the testing error of Net-A and Net-B are close. We obtain evidence that supports our hypothesis by setting the scale as 10, 15, 20, 25, and other larger numbers. For each scale, we repeat the experiment for fifty times.

7.2 Results

In Figure 3, we display a representative result where the scale is set as 10. The rest of experiment data is concluded in the supplementary material [Mo and Chen, 2019].

The results suggest that ResNet structure has a lower generalization bound than DNN, while the test error of two models are close (more than 95% of the data holds \( A_{GB} > B_{GB} \)). The experiment implies that the ResNets structure contributes to better generalization properties.

8 Conclusion

8.1 Guidance on parameters to avoid overfitting

According to theorem 4.3, the following settings can improve the network structures’ generalization capacity: (1).\( 1/p + 1/q >= 1 \); (2).As the \( p,q \)-norm of each matrix \( M_i \) is constrained to be less than \( c_i \), we can set \( c_i \) as constants that small enough to force generalization bound to be a small value; (3).The residual connection structures (short cut) render the generalization bound smaller, which explains why ResNets generalizes better than DNN does.

8.2 Future work

With the guidance, we can develop efficient algorithms to train Weight-Normalized networks with small generalization bound. In the future, we will focus on the generalization bound when it is restricted on a smaller function space (i.e. a vicinity of a local maximal solution) for further exploration of the generalization properties.
