**Abstract**

We present NeurASP, a simple extension of answer set programs by embracing neural networks. By treating the neural network output as the probability distribution over atomic facts in answer set programs, NeurASP provides a simple and effective way to integrate sub-symbolic and symbolic computation. We demonstrate how NeurASP can make use of a pre-trained neural network in symbolic computation and how it can improve the neural network’s perception result by applying symbolic reasoning in answer set programming. Also, NeurASP can make use of ASP rules to train a neural network better so that a neural network not only learns from implicit correlations from the data but also from the explicit complex semantic constraints expressed by the rules.

**1 Introduction**

The integration of low-level perception with high-level reasoning is one of the oldest problems in Artificial Intelligence. Today, the topic is revisited with the recent rise of deep neural networks. Several proposals were made to implement the reasoning process in complex neural network architectures, e.g., [Cohen et al., 2018; Rottkäschel and Riedel, 2017; Donadello et al., 2017; Kazemi and Poole, 2018; Šourek et al., 2015; Palm et al., 2018; Lin et al., 2019]. However, it is still not clear how complex and high-level reasoning, such as default reasoning [Reiter, 1980], ontology reasoning [Baader et al., 2003], and causal reasoning [Pearl, 2000], can be successfully computed by these approaches. The latter subject has been well-studied in the area of knowledge representation (KR), but many KR formalisms, including answer set programming (ASP) [Lifschitz, 2008; Brewka et al., 2011], are logic-oriented and do not incorporate high-dimensional vector space and pre-trained models for perception tasks as handled in deep learning, which limits the applicability of KR in many practical applications involving data and uncertainty.

In this paper, we present a simple extension of answer set programs by embracing neural networks. Following the idea of DeepProbLog [Manhaeve et al., 2018], by treating the neural network output as the probability distribution over atomic facts in answer set programs, the proposed NeurASP provides a simple and effective way to integrate sub-symbolic and symbolic computation.

We demonstrate how NeurASP can be useful for some tasks where both perception and reasoning are required. Reasoning can help identify perception mistakes that violate semantic constraints, which in turn can make perception more robust. For example, a neural network for object detection may return a bounding box and its classification “car,” but it may not be clear whether it is a real car or a toy car. The distinction can be made by applying reasoning about the relations with the surrounding objects and using commonsense knowledge. When it is unclear whether a round object attached to the car is a wheel or a doughnut, the reasoner could conclude that it is more likely to be a wheel by applying commonsense knowledge. In the case of a neural network that recognizes digits in a given Sudoku board, the neural network may get confused if a digit next to 1 in the same row is 1 or 2, but the reasoner could conclude that it cannot be 1 due to the constraints for Sudoku.

Another benefit of this hybrid approach is that it alleviates the burden of neural networks when the constraints/knowledge are already given. Instead of building a large end-to-end neural network that learns to solve a Sudoku puzzle given as an image, we let a neural network only do digit recognition and use ASP to find the solution of the recognized board. This makes the design of the neural network simpler and the required training dataset much smaller. Also, when we need to solve some variation of Sudoku, such as Anti-Knight and Offset Sudoku, the required modification is simpler than training another large neural network from scratch to solve the new puzzle.

NeurASP can also be used to train a neural network together with rules so that a neural network not only learns from implicit correlations from the data but also from explicit complex semantic constraints expressed by ASP rules. The **semantic loss** [Xu et al., 2018] obtained from the reasoning module can be backpropagated into the rule layer and then further into neural networks via neural atoms. This sometimes makes a neural network learn better even with fewer data.

The paper is organized as follows. Section 2 introduces
the syntax and the semantics of NeurASP. Section 3 illustrates how reasoning in NeurASP can enhance the perception result by considering relations among objects perceived by pre-trained neural networks. Section 4 presents learning in NeurASP where ASP rules work as a semantic regularizer for training neural networks. Section 5 examines related works and Section 6 concludes.

The implementation of NeurASP, as well as the codes used for the experiments, is publicly available online at https://github.com/azreasoners/NeurASP.

2 NeurASP

We present the syntax and the semantics of the NeurASP language.

2.1 Syntax

We assume that neural network $M$ allows an arbitrary tensor as input whereas the output is a matrix in $\mathbb{R}^{e \times n}$, where $e$ is the number of random events predicted by the neural network and $n$ is the number of possible outcomes for each random event. Each row of the matrix represents the probability distribution of the outcomes of each event. For example, if $M$ is a neural network for MNIST digit classification, then the input is a tensor representation of a digit image, $e$ is 1, and $n$ is 10. If $M$ is a neural network that outputs a Boolean value for each edge in a graph, then $e$ is the number of edges and $n$ is 2. Given an input tensor $t$, we denote the output matrix of $M$. The value $M(t)[i,j]$ ($i \in \{1, \ldots, e\}$, $j \in \{1, \ldots, n\}$) is the probability of the $j$-th outcome of the $i$-th event upon the input $t$.

In NeurASP, the neural network $M$ above can be represented by a neural atom of the form

$$nn(m(e, t), [v_1, \ldots, v_n]),$$

where (i) $nn$ is a reserved keyword to denote a neural atom; (ii) $m$ is an identifier (symbolic name) of the neural network $M$; (iii) $t$ is a list of terms that serves as a “pointer” to an input tensor; related to it, there is a mapping $D$ (implemented by an external Python code) that turns $t$ into an input tensor; (iv) $v_1, \ldots, v_n$ represent all $n$ possible outcomes of each of the $e$ random events.

Each neural atom (1) introduces propositional atoms of the form $c = v$, where $c \in \{m_1(t), \ldots, m_e(t)\}$ and $v \in \{v_1, \ldots, v_n\}$. The output of the neural network provides the probabilities of the introduced atoms (defined in Section 2.2).

Example 1 Let $M_{digit}$ be a neural network that classifies an MNIST digit image. The input of $M_{digit}$ is (a tensor representation of) an image and the output is a matrix in $\mathbb{R}^{1 \times 10}$. The neural network can be represented by the neural atom

$$nn(digit(1, d), [0, 1, 2, 3, 4, 5, 6, 7, 8, 9]),$$

which introduces propositional atoms $digit_1(d) = 0$, $digit_1(d) = 1, \ldots, digit_9(d) = 9$.

Example 2 Let $M_{sp}$ be another neural network for finding the shortest path in a graph with 24 edges. The input is a tensor that encodes the graph and the start/end nodes of the path, and the output is a matrix in $\mathbb{R}^{24 \times 2}$. This neural network can be represented by the neural atom

$$nn(sp(24, g), [true, false]).$$

A NeurASP program $Pi$ is the union of $Pi^{asp}$ and $Pi^{nn}$, where $Pi^{asp}$ is a set of propositional rules (standard rules as in ASP-Core 2 [Calimeri et al., 2020]) and $Pi^{nn}$ is a set of neural atoms. Let $\sigma^{nn}$ be the set of all atoms $m_i(t) = v_j$ that is obtained from the neural atoms in $Pi^{nn}$ as described above. We require that, in each rule $Head \leftarrow Body$ in $Pi^{asp}$, no atoms in $\sigma^{nn}$ appear in $Head$.

We could allow schematic variables into $Head$, which are understood in terms of grounding as in standard answer set programs. We find it convenient to use rules of the form

$$nn(m(e, t), [v_1, \ldots, v_n]) \leftarrow Body$$

where $Body$ is either identified by $\top$ or $\bot$ during grounding so that (2) can be viewed as an abbreviation of multiple (variable-free) neural atoms (1).

Example 3 An example NeurASP program $Pi_{digit}$ is as follows, where $d_1$ and $d_2$ are terms representing two images. Each image is classified by neural network $M_{digit}$ as one of the values in $\{0, \ldots, 9\}$. The addition of two digit-images is the sum of their values.

$$\text{img}(d_1). \text{img}(d_2).$$

$$nn(digit(1, X), [0, 1, 2, 3, 4, 5, 6, 7, 8, 9]) \leftarrow \text{img}(X).$$

$$\text{addition}(A, B, N) \leftarrow \text{digit}_1(A) = N_1, \text{digit}_1(B) = N_2,$$

$$N = N_1 + N_2.$$  

The neural network $M_{digit}$ outputs 10 probabilities for each image. The addition is applied once the digits are recognized and its probability is induced from the perception output as we explain in the next section.

2.2 Semantics

For any NeurASP program $Pi$, we first obtain its ASP counterpart $Pi'$ where each neural atom (1) is replaced with the set of rules

$$\{m_i(t) = v_1; \ldots; m_i(t) = v_n\} = 1 \text{ for } i \in \{1, \ldots, e\}.$$  

The above rule (in the language of CLINGO) means to choose exactly one atom in between the set braces.\(^1\) We define the stable models of $Pi$ as the stable models of $Pi'$. To define the probability of a stable model, we first define the probability of an atom $m_i(t) = v_j$ in $\sigma^{nn}$. Recall that there is an external mapping $D$ that turns $t$ into a specific input tensor of $M$. The probability of each atom $m_i(t) = v_j$ is defined as $M(D(t))[i, j]$:

$$P_m(m_i(t) = v_j) = M(D(t))[i, j].$$

For instance, recall that the output matrix of $M_{digit}(D(d))$ in Example 3 is in $\mathbb{R}^{1 \times 10}$. The probability of atom $digit_1(d) = k$ is $M_{digit}(D(d))[1, k + 1]$.

Given an interpretation $I$, by $I|_{\sigma^{nn}}$, we denote the projection of $I$ onto $\sigma^{nn}$. By $\text{Num}(I|_{\sigma^{nn}}, Pi)$, we denote the number of stable models of $Pi$ that agree with $I|_{\sigma^{nn}}$ on $\sigma^{nn}$.

\(^1\)In practice, each atom $m_i(t) = v$ is written as $m(i, t, v)$.
The probability of a stable model $I$ of $\Pi$ is defined as the product of the probability of each atom $c = v$ in $I|_{\sigma^{nn}}$, divided by the number of stable models of $\Pi$ that agree with $I|_{\sigma^{nn}}$ on $\sigma^{nn}$. That is, for any interpretation $I$,

$$P_{\Pi}(I) = \begin{cases} \prod_{c = v \in I|_{\sigma^{nn}}} P_{\Pi}(c = v) & \text{if } I \text{ is a stable model of } \Pi; \\ 0 & \text{otherwise.} \end{cases}$$

An observation is a set of ASP constraints (i.e., rules of the form $\bot \leftarrow \text{Body}$). The probability of an observation $O$ is defined as

$$P_{\Pi}(O) = \sum_{I \models O} P_{\Pi}(I)$$

($I \models O$ denotes that $I$ satisfies $O$).

The probability of the set $O = \{O_1, \ldots, O_n\}$ of observations is defined as the product of the probability of each $O_i$:

$$P_{\Pi}(O) = \prod_{O_i \in O} P_{\Pi}(O_i).$$

**Example 3 Continued** The ASP program $\Pi'_\text{digit}$, which is the ASP counterpart of $\Pi_\text{digit}$, is obtained from (3) by replacing the third rule with

$$\{\text{digit}_i(d_1) = 0; \ldots; \text{digit}_i(d_1) = 9\} = 1.$$ 

The following are the stable models of $\Pi_\text{digit}$, i.e., the stable models of $\Pi'_\text{digit}$.

$$I_1 = \{\text{digit}_1(d_1) = 0, \text{digit}_1(d_2) = 0, \text{addition}(d_1, d_2, 0), \ldots\},$$
$$I_2 = \{\text{digit}_1(d_1) = 0, \text{digit}_1(d_2) = 1, \text{addition}(d_1, d_2, 1), \ldots\},$$
$$I_3 = \{\text{digit}_1(d_1) = 1, \text{digit}_1(d_2) = 0, \text{addition}(d_1, d_2, 1), \ldots\},$$
$$\ldots$$
$$I_{100} = \{\text{digit}_1(d_1) = 9, \text{digit}_1(d_2) = 9, \text{addition}(d_1, d_2, 18), \ldots\}.$$

And their probabilities are as follows:

$$P_{\Pi}(I_1) = M_{\text{digit}}(\text{D}(d_1))[1, 1] \times M_{\text{digit}}(\text{D}(d_2))[1, 1],$$
$$\ldots$$
$$P_{\Pi}(I_{100}) = M_{\text{digit}}(\text{D}(d_1))[1, 10] \times M_{\text{digit}}(\text{D}(d_2))[1, 10].$$

The probability of $O = \{\leftarrow \nono \text{addition}(d_1, d_2, 1)\}$ is

$$P_{\Pi}(O) = P_{\Pi}(I_2) + P_{\Pi}(I_3).$$

### 3 Inference with NeurASP

We implemented NeurASP by interfacing PyTorch [Adam et al., 2017] with CLINGO [Gebser et al., 2011]. PyTorch takes care of neural network processing including data loading and the mapping $\text{D}$ that turns pointer terms in neural atoms to input tensors. Computing the probability of a stable model is done by calling CLINGO and post-processing in PyTorch. This section illustrates how the implementation can be useful in reasoning about relations among objects recognized by neural networks.

### 3.1 Commonsense Reasoning about Image

Suppose we have a neural network $M_{\text{label}}$ that outputs classes of objects in the bounding boxes as in YOLO. The following rule asserts that the neural network $M_{\text{label}}$ classifies the bounding box $B$ into one of $\{\text{car}, \text{cat}, \text{person}, \text{truck}, \text{other}\}$, where $B$ is at location $(X_1, Y_1, X_2, Y_2)$ in image $I$:

$$\text{nn(label}(I, B), [\text{car}, \text{cat}, \text{person}, \text{truck}, \text{other}]) \leftarrow \text{box}(I, B, X_1, Y_1, X_2, Y_2).$$

Consider the two images $i_1$ and $i_2$ in Figure 1. The bounding boxes can be represented by the following facts.

$$\text{box}(i_1, b_1, 100, 0, 450, 350).$$
$$\text{box}(i_1, b_2, 300, 300, 500, 400).$$
$$\ldots$$

The first rule says that there is a bounding box $b_1$ (i.e., the red box with a child) in image $i_1$, and the coordinates of its left-top and right-bottom corners are $(100, 0)$ and $(450, 350)$.

Below we describe rules that allow for reasoning about the recognized objects. The following rules describe the general size relation between objects.

$$\text{smaller(}\text{car}, \text{person}).$$
$$\text{smaller(}\text{person}, \text{car}).$$
$$\text{smaller(}\text{person}, \text{truck}).$$
$$\text{smaller}(X, Y) \leftarrow \text{smaller}(X, Z), \text{smaller}(Z, Y).$$

Next is the rule asserting that by default we conclude the size relationship as described above.

$$\text{smaller}(I, B_1, B_2) \leftarrow \nono \text{not}\sim\text{smaller}(I, B_1, B_2).$$
$$\text{label}_1(I, B_1) = L_1, \text{label}_1(I, B_2) = L_2, \text{smaller}(L_1, L_2).$$

(The $\sim$ symbol stands for strong negation in ASP, which asserts explicit falsity.)

On the other hand, there are some exceptions, for instance,

$$\nono\text{smaller}(I, B_2, B_1) \leftarrow \text{box}(I, B_1, X_1, Y_1, X_2, Y_2),$$
$$\text{box}(I, B_2, X'_1, Y'_1, X'_2, Y'_2),$$
$$Y'_2 \geq Y_2',$$
$$|X_1 - X_2| \times |Y_1 - Y_2| < |X'_1 - X'_2| \times |Y'_1 - Y'_2|.$$
The neural network model $M_{\text{label}}$ outputs that the red boxes are persons, the yellow boxes are cars, and the green box is a truck. Upon this input and the rules above, NeurASP allows us to derive that the two cars in image $i_1$ are toy cars, whereas the two cars in image $i_2$ are not: although they are surrounded by smaller boxes than those of humans, their boxes are not closer to the camera.

### 3.2 Example: Solving Sudoku Puzzle in Image

Consider the task of solving a Sudoku puzzle given as an image. In NeurASP, we could use a neural network to recognize the digits in the given puzzle and use an ASP solver to compute the solution instead of having a single network that accounts for both perception and solving.

We use the following NeurASP program $\Pi_{\text{sudoku}}$ to first identify the digits in each grid cell on the board and then find the solution by assigning digits to all empty grid cells. $^3$

\[
\text{\% identify the number in each of the 81 positions} \\
\text{nn(identify}(81, \text{img}), \{\text{empty, 1, 2, 3, 4, 5, 6, 7, 8, 9}\}).
\]

\[
\text{\% assign one number N to each position (R,C)} \\
a(R,C,N) :- \text{identify}(\text{Pos, img, N}), R=\text{Pos}/9, C=\text{Pos}\%9, N!=\text{empty}. \\
\{a(R,C,N): N=1..9\}=1 :- \text{identify}(\text{Pos, img, empty}), R=\text{Pos}/9, C=\text{Pos}\%9.
\]

\[
\text{\% no number repeats in the same row} \\
:- a(R1,C1,N), a(R2,C2,N), C1!=C2.
\]

\[
\text{\% no number repeats in the same column} \\
:- a(R1,C,N), a(R2,C,N), R1!=R2.
\]

\[
\text{\% no number repeats in the same 3x3 box} \\
:- a(R,C,N), a(R1,C1,N), R1!=R, C1!=C, ((R/3)*3 + C/3) = ((R1/3)*3 + C1/3).
\]

The neural network model $M_{\text{identify}}$ is rather simple. It is composed of 5 convolutional layers with dropout, a max pooling layer, and a $1 \times 1$ convolutional layer followed by softmax. Given a Sudoku board image (.png file), neural network $M_{\text{identify}}$ outputs a matrix in $\mathbb{R}^{81 \times 10}$, which represents the probabilities of the values ($\text{empty}, 1, \ldots, 9$) in each of the 81 grid cells. The network $M_{\text{identify}}$ is pre-trained using $(\text{image, label})$ pairs, where each $\text{image}$ is a Sudoku board image generated by OpenSky Sudoku Generator (http://www.opensky.ca/~jdhildeb/software/sudokugen/) and each $\text{label}$ is a vector of length 81 in which 0 is used to represent an empty cell at that position.

Let $\text{Acc}_{\text{identify}}$ denote the accuracy of identifying all empty cells and the digits on the board given as an image without making a single mistake in a grid cell. Let $\text{Acc}_{\text{sol}}$ denote the accuracy of solving a given Sudoku board without making a single mistake in a grid cell. Let $r$ be the third rule of $\Pi_{\text{sudoku}}$, that is,

\[
\{a(R,C,N): N=1..9\}=1 :- \text{identify}(\text{Pos, img, empty}), R=\text{Pos}/9, C=\text{Pos}\%9.
\]

Table 1 compares $\text{Acc}_{\text{identify}}$ of each of $M_{\text{identify}}$, NeurASP program $\Pi_{\text{sudoku}} \setminus r$ with $M_{\text{identify}}$, NeurASP program $\Pi_{\text{sudoku}}$ with $M_{\text{identify}}$, as well as $\text{Acc}_{\text{sol}}$ of $\Pi_{\text{sudoku}}$ with $M_{\text{identify}}$.

### Table 1: Sudoku: Accuracy on test data

Intuitively, $\Pi_{\text{sudoku}} \setminus r$ only checks whether the identified numbers (by neural network $M_{\text{identify}}$) satisfy the three constraints (the last three rules of $\Pi_{\text{sudoku}}$), while $\Pi_{\text{sudoku}}$ further checks whether there exists a solution given the identified numbers. As shown in Table 1, the use of reasoning in NeurASP program $\Pi_{\text{sudoku}} \setminus r$ improves the accuracy $\text{Acc}_{\text{identify}}$ of the neural network $M_{\text{identify}}$ as explained in the introduction. The accuracy $\text{Acc}_{\text{identify}}$ is further improved by trying to solve Sudoku completely using $\Pi_{\text{sudoku}}$.

Note that the solution accuracy $\text{Acc}_{\text{sol}}$ of $\Pi_{\text{sudoku}}$ is equal to the perception accuracy $\text{Acc}_{\text{identify}}$ of $\Pi_{\text{sudoku}}$ since ASP yields a 100% correct solution once the board is correctly identified.

Palm et al. [2018] use a Graph Neural Network to solve Sudoku but the work restricts attention to textual input of the Sudoku board, not images as we do. Their work achieves 96.6% accuracy after training with 216,000 examples. In comparison, even with the more challenging task of accepting images as input, the number of training examples we used is $15 \sim 25$ (albeit it’s tailored to OpenSky Sudoku Generator), which is much less than the number of training examples used in [Palm et al., 2018]. Our work takes advantage of the fact that in a problem like Sudoku, where the constraints are explicitly given, a neural network only needs to focus on perception tasks, which is simpler than learning the perception and reasoning together.

Furthermore, using the same trained perception neural network $M_{\text{identify}}$, we can solve some elaborations of Sudoku problems by adding the following rules to $\Pi_{\text{sudoku}}$.

#### [Anti-knight Sudoku]

| No number repeats at a knight move:
| $:- a(R1,C1,N), a(R2,C2,N), |R1-R2|+|C1-C2|=3$. |

#### [Sudoku-X]

| No number repeats at the diagonals:
| $:- a(R1,C1,N), a(R2,C2,N), R1=C1, R2=C2, R1!=R2$. |
| $:- a(R1,C1,N), a(R2,C2,N), R1+C1=8, R2+C2=8, R1!=R2$. |

With the neural network only approach, since the neural network needs to learn both perception and reasoning, each of the above variations would require training a different complex model with a big dataset. However, with NeurASP, the neural network only needs to recognize digits on the board. Thus solving each Sudoku variation above uses the same pre-trained model for the image input and we only need to add the aforementioned rules to $\Pi_{\text{sudoku}}$.

---

$^3$The expression $\{a(R, C, N): N = 1..9\} = 1$ is a shorthand for $\{a(R, C, 1), \ldots; a(R, C, 9)\} = 1$ in the language of CLINGO.
Some Sudoku variations, such as Offset Sudoku, are in colored images. In this case, we need to increase the number of channels of $M_{\text{identify}}$ from 1 to 3 (r-g-b), and need to retrain the neural network with the colored images. Although not completely elaboration tolerant, compared to the neural network only approach, this is significantly simpler. For instance, the number of training data needed to get 100% perception accuracy for Offset Sudoku ($Acc_{\text{identify}}$) is 70, which is still much smaller than what the end-to-end Sudoku solver would require. Using the new network trained, we only need to add the following rule to $\Pi_{\text{sudoku}}$.

**[Offset Sudoku]** No number repeats at the same relative position in 3x3 boxes

$$:- a(R1,C1,N), a(R2,C2,N), R1 \neq R2, C1 \neq C2.$$ 

4 Learning in NeurASP

We show how the semantic constraints expressed in NeurASP can be used to train neural networks better.

4.1 Gradient Ascent with NeurASP

In this section, we denote a NeurASP program by $\Pi(\theta)$ where $\theta$ is the set of the parameters in the neural network models associated with $\Pi$. Assume a NeurASP program $\Pi(\theta)$ and a set $O$ of observations such that $P_{\Pi(\theta)}(O) > 0$ for each $O \in O$. The task is to find $\theta$ that maximizes the log-likelihood of observations $O$ under program $\Pi(\theta)$, i.e.,

$$\hat{\theta} \in \arg\max_{\theta} \log(P_{\Pi(\theta)}(O)).$$

which is equivalent to

$$\hat{\theta} \in \arg\max_{\theta} \sum_{O \in O} \log(P_{\Pi(\theta)}(O)).$$

Let $p$ denote the probabilities of the atoms in $\sigma_{\text{nn}}$. Since $p$ is indeed the outputs of the neural networks in $\Pi(\theta)$, we can compute the gradient of $p$ w.r.t. $\theta$ through backpropagation. Then the gradient of $\sum_{O \in O} \log(P_{\Pi(\theta)}(O))$ w.r.t. $\theta$ is

$$\frac{\partial}{\partial \theta} \sum_{O \in O} \log(P_{\Pi(\theta)}(O)) = \sum_{O \in O} \frac{\partial \log(P_{\Pi(\theta)}(O))}{\partial \theta} \times \frac{\partial p}{\partial \theta},$$

where $\frac{\partial p}{\partial \theta}$ can be computed through the usual neural network backpropagation, while $\frac{\partial \log(P_{\Pi(\theta)}(O))}{\partial \theta}$ for each $p \in p$ can be computed as follows.

**Proposition 1** Let $\Pi(\theta)$ be a NeurASP program and let $O$ be an observation such that $P_{\Pi(\theta)}(O) > 0$. Let $p$ denote the probability of an atom $c = v$ in $\sigma_{\text{nn}}$, i.e., $p$ denotes $P_{\Pi(\theta)}(c = v)$. We have that

$$\frac{\partial \log(P_{\Pi(\theta)}(O))}{\partial p} = \frac{\sum_{I \subseteq O} P_{\Pi(\theta)}(I)}{P_{\Pi(\theta)}(O)} - \sum_{I \subseteq O} \frac{P_{\Pi(\theta)}(I)}{P_{\Pi(\theta)}(O)} \sum_{I \subseteq O'} \frac{P_{\Pi(\theta)}(I)}{P_{\Pi(\theta)}(O')} \times \frac{\partial p}{\partial \theta}.$$ 

Intuitively, the proposition tells us that each interpretation $I$ that satisfies $O$ tends to increase the value of $p$ if $I \models c = v$, and decrease the value of $p$ if $I \models c = v'$ such that $v' \neq v$. NeurASP internally calls CLINGO to find all stable models $I$ of $\Pi(\theta)$ that satisfy $O$ and uses PyTorch to obtain the probability of each atom $c = v$ in $\sigma_{\text{nn}}$.

4.2 Experiment 1: Learning Digit Classification from Addition

All experiments in Section 4 were done on Ubuntu 18.04.2 LTS with two 10-cores CPU Intel(R) Xeon(R) CPU E5-2640 v4 @ 2.40GHz and four GP104 [GeForce GTX 1080].

The digit addition problem is a simple example used in [Manhaeve et al., 2018] to illustrate DeepProbLog’s ability for both logical reasoning and deep learning. The task is, given a pair of digit images (MNIST) and their sum as the observation $O$. The training target is to maximize $\log(P_{\Pi_{\text{digit}}}(O))$.

Figure 2 shows how the forward and the backward propagations are done for NeurASP program $\Pi_{\text{digit}}$ in Example 3. The left-to-right direction is the forward computation of the neural network extended with the rule layer, whose output is the probability of the observation $O$. The right-to-left direction shows how the gradient from the rule layer is backpropagated further into the neural network by the chain rule to update all neural network parameters so as to find the parameter values that maximize the probability of the given observation.

Figure 3 shows the accuracy on the test data after each training iteration. The method CNN denotes the baseline used in [Manhaeve et al., 2018] where a convolutional neural network (with more parameters) is trained to classify the concatenation of the two images into the 19 possible sums. As we can see, the neural networks trained by NeurASP and DeepProbLog converge much faster than CNN and have almost the same accuracy at each iteration. However, NeurASP spends much less time on training compared to DeepProbLog. This is because DeepProbLog constructs an SDD (Sequential Decision Diagram) at each iteration for each training instance.
In section 3.2, we used a neural network \( M_{\text{identify}} \) to identify the numbers on a Sudoku board and used ASP rules to solve the Sudoku problem. In this section, we use a neural network to learn to solve Sudoku problems. The task is, given the textual representation of an unsolved Sudoku board (in the form of a \( 9 \times 9 \) matrix where an empty cell is represented by 0), to let a neural network learn to predict the solution of the Sudoku board.

We use the neural network \( M_{\text{sol}} \) from [Park, 2018] as the baseline. \( M_{\text{sol}} \) is composed of 9 convolutional layers and a 1x1 convolution layer followed by softmax. Park trained \( M_{\text{sol}} \) using 1 million examples and achieved 70% accuracy using an "inference trick": instead of predicting digits for all empty cells at once, which leads to a poor accuracy, the most probable grid-cell value was predicted one by one. Using an "inference trick": instead of predicting digits for all empty cells at once, which leads to a poor accuracy, the most probable grid-cell value was predicted one by one.

Since the current NeurASP implementation is not as scalable as neural network training, training on 1 million examples takes too long. Thus, we construct a dataset of 63,000 + 1000 (config,label) pairs for training and testing. Using Park’s method on this relatively small dataset, we observe that \( M_{\text{sol}} \)'s highest whole-board accuracy \( Acc_{\text{sol}} \) is only 29.1% and \( M_{\text{sol}} \)'s highest grid-cell accuracy is only 89.3% after 63 epochs of training.

We get a better result by training \( M_{\text{sol}} \) with the NeurASP program \( \Pi_{\text{sol}} \). The program is almost the same as \( \Pi_{\text{identify}} \) in Section 3.2 except that it uses \( M_{\text{sol}} \) in place of \( M_{\text{identify}} \) and the first three rules of \( \Pi_{\text{identify}} \) are replaced with

\[
nn(sol(81, img), [1,2,3,4,5,6,7,8,9]).
\]

\[
a(R,C,N) :- \text{identify}(sol, img, N), \text{R=Pos/9, C=Pos\9}.
\]

\[
\text{because we do not have to assign the value empty in solving Sudoku.}
\]

5The percentage of Sudoku examples that are correctly solved.

6The percentage of grid cells having correct digits regardless whether the Sudoku solution is correct.

We trained \( M_{\text{sol}} \) using NeurASP where the training target is to maximize the probability of all stable models that satisfy the observation. On the same test data, after 63 epochs of training, the highest whole-board accuracy of \( M_{\text{sol}} \) trained this way is 66.5% and the highest grid-cell accuracy is 96.9% (In other words, we use rules only during training and not during testing). This illustrates that such structured knowledge represented in NeurASP may help train a neural network significantly better.

## 4.4 Experiment 3: Learning Shortest Path (SP)

The experiment is about, given a graph and two points, finding the shortest path between them. We use the dataset from [Xu et al., 2018], which was used to demonstrate the effectiveness of semantic constraints for enhanced neural network learning. Each example is a 4 by 4 grid \( G = (V, E) \), where \( |V| = 16, |E| = 24 \). The source and the destination nodes are randomly picked up, and 8 edges are randomly removed to increase the difficulty. The dataset is divided into 60/20/20 train/validation/test examples.

The following NeurASP program

\[
nn(sp(24, g), [true, false]).
\]

\[
sp(0,1) :- sp(1,g,true).
\]

\[
\cdots
\]

\[
sp(X,Y) :- sp(Y,X).
\]

together with the union of the following 4 constraints defines the shortest path.

\[
\begin{align*}
% \{ nr \} & 1. \text{No removed edges should be predicted} \\
& :- sp(X,g,true), \text{removed}(X). \\
% \{ p \} & 2. \text{Prediction must form a simple path, i.e.,} \\
& \text{the degree of each node must be either 0 or 2} \\
& :- X=0..15, \text{#count}(Y: sp(X,Y)) = 1. \\
& :- X=0..15, \text{#count}(Y: sp(X,Y)) \geq 3. \\
% \{ r \} & 3. \text{Every 2 nodes in the prediction must be} \\
& \text{reachable} \\
& \text{reachable}(X,Y) :- sp(X,Y). \\
& \text{reachable}(X,Y) :- \text{reachable}(X,Z), sp(Z,Y). \\
& :- sp(X,A), sp(Y,B), \text{not reachable}(X,Y). \\
% \{ o \} & 4. \text{Predicted path should contain least edges} \\
& \text{~} sp(X,g,true). [1, X]
\end{align*}
\]

In this experiment, we trained the same neural network model \( M_{\text{sp}} \) as in [Xu et al., 2018], a 5-layer Multi-Layer Perceptron (MLP), but with 4 different settings: (i) MLP only; (ii) together with NeurASP with the simple-path constraint \( (p) \) (which is the only constraint used in [Xu et al., 2018]); (iii) together with NeurASP with simple-path, reachability, and optimization constraints \( (p-r-o) \); and (iv) together with NeurASP with all 4 constraints \( (p-r-o-nr) \).

Table 2 shows that, after 500 epochs of training, the percentage of the predictions on the test data that satisfy each of the constraints \( p, r, o, nr \), the path constraint (i.e., \( p-r \)).

\[
\begin{align*}
\text{Table 2 shows that, after 500 epochs of training, the percentage of the predictions on the test data that satisfy each of the constraints } p, r, o, nr, \text{the path constraint (i.e., } p-r).\n\end{align*}
\]

\[
\begin{align*}
\text{\( sp(X,g,true) \) means edge } X \text{ is in the shortest path. } sp(X,Y) \text{ means there is a path between nodes } X \text{ and } Y \text{ in the shortest path.} \\
\text{Other combinations are either meaningless (e.g., } o \text{) or having similar results (e.g. } p-r \text{ is similar to } p). \\
\end{align*}
\]

Table 2: Shortest Path: Accuracy on Test Data: columns denote MLPs trained with different rules; each row represents the percentage of predictions that satisfy the constraints

The shortest path constraint (i.e., p-r-o-nr), and the accuracy w.r.t. the ground truth.

The accuracies for the first experiment (MLP Only) show that $M_{sp}$ is not trained well only by minimizing the cross-entropy loss of its prediction: $100 - 28.3 = 71.7\%$ of the predictions are not even a simple-path.

In the remaining experiments (MLP ($\cdot$)), our training target is changed to maximizing the probability of all stable models under certain constraints. The accuracies under the 2nd and 3rd experiments (MLP (p) and MLP (p-r-o) columns) increase significantly, showing that (i) including such structured knowledge helps the training of the neural network and (ii) the more structured knowledge included, the better $M_{sp}$ is trained under NeurASP. Compared to the results from [Xu et al., 2018], $M_{sp}$ trained by NeurASP with the simple-path constraint p (in the 2nd experiment MLP (p) column) obtains a similar accuracy on predicting the label (28.9% v.s. 28.5%) but a higher accuracy on predicting a simple-path (96.6% v.s. 69.9%).

In the 4th experiment (MLP (p-r-o-nr) column) where we added the constraint nr saying that “no removed edges can be predicted”, the accuracies go down. This is because the new constraint nr is about randomly removed edges, changing from one example to another, which is hard to be generalized.

5 Related Work

Recent years have observed the rising interests of combining perception and reasoning. As mentioned, the work on DeepProbLog [Manhaeve et al., 2018] is closest to our work. Some differences are: (i) The computation of DeepProbLog relies on constructing circuits such as sequential decision diagrams (SDD) whereas we use an ASP solver internally. (ii) NeurASP employs expressive reasoning originating from answer set programming, such as defaults, aggregates, and optimization rules. This not only gives more expressive reasoning but also allows the more semantic-rich constructs as guide to learning. (iii) DeepProbLog requires each training data to be a single atom, while NeurASP allows each training data to be arbitrary propositional formulas.

Also related is using the semantic constraints to train neural networks better [Xu et al., 2018], but the constraints used in that work are simple propositional formulas whereas we use answer set programming language, in which it is more convenient to encode complex KR constraints. Logic Tensor Network [Donadello et al., 2017] is also related in that it uses neural networks to provide fuzzy values to atoms.

Another approach is to embed logic rules in neural networks by representing logical connectives by mathematical operations and allowing the value of an atom to be a real number. For example, Neural Theorem Prover (NTP) [Röcktäschel and Riedel, 2017] adopts the idea of dynamic neural module networks [Andreas et al., 2016] to embed logic conjunction and disjunction in and/or-module networks. A proof-tree like end-to-end differentiable neural network is then constructed using Prolog’s backward chaining algorithm with these modules. Another method that also constructs a proof-tree like neural network is TensorLog [Cohen et al., 2018], which uses matrix multiplication to simulate belief propagation that is tractable under the restriction that each rule is negation-free and can be transformed into a polytree.

Graph neural network (GNN) [Kipf and Welling, 2017] is a neural network model that is gaining more attention recently. Since a graph can encode objects and relations between objects, by learning message functions between the nodes, one can perform certain relational reasoning. For example, in [Palm et al., 2018], it is shown that GNN can do well on Sudoku (given as textual input though). However, this is still restrictive compared to the more complex reasoning that KR formalisms provide.

Neuro-Symbolic Concept Learner [Mao et al., 2019] separates between visual perception and symbolic reasoning. It shows the data-efficiency by using only 10% of the training data and achieving the state-of-the-art 98% accuracy on CLEVR dataset. Our results are similar in the sense that using symbolic reasoning, we could use fewer data to achieve a high accuracy.

NeurASP is similar to LP$^{MLN}$ [Lee and Wang, 2016] in the sense that they are both probabilistic extensions of ASP and their semantics are defined by translations into ASP [Lee and Yang, 2017]. LP$^{MLN}$ allows any rules to be weighted, whereas NeurASP uses standard ASP rules.

6 Conclusion

We showed that NeurASP can improve the neural network’s perception result by applying reasoning over perceived objects and also can help neural network learn better by compensating the small size data with knowledge and constraints. Since NeurASP is a simple integration of ASP with neural networks, it retains each of ASP and neural networks in individual forms, and can directly utilize the advances in each of them.

The current implementation is a prototype and not highly scalable due to a naive computation of enumerating stable models. The future work includes how to make learning faster, and also analyzing the effects of the semantic constraints more systematically.
